## Description

This invention pertains generally to a therapeutic agent delivery device for treating diseases of the mouth, and particularly periodontal diseases.

Periodontal disease is a condition caused by a pathogenic microbial ecology established within the gingival sulcus which deepens to become a periodontal pocket. This microbial ecology, located deep within the periodontal pocket, differs greatly from that of the superficial oral environment by being more anaerobic, having a larger number of Gram negative organisms, and having a greater proportion of motile species.

Several factors impede the diffusion of medicinal agents when applied to the superficial periodontal tissues. Anatomically, the gum tissue is closely adapted to the neck of the teeth, mechanically restricting the diffusional pathway. In addition, a fluid termed gingival crevice fluid, with the approximate composition of plasma, permeates the periodontal environment and is continually produced by the diseased periodontal tissues at a rate of 10 to 100 microliters per hour. This fluid, emanating from the diseased pocket lining, creates a net outward flow further impeding the introduction of medications from superficially applied drug delivery devices. These interferences are sufficiently effective to insulate the pocket environment to the extent that saliva does not penetrate, and topically applied medicinal agents have been found largely ineffectual in the treatment of established periodontitis.

Although mouth rinses may be effective in the reduction of superficial gingivitis resulting from poor home care procedures, the effective radius of action of these agents does not extend to the periodontal pocket. Introduction of antibacterial agents in solution form into the periodontal pocket is similarly ineffective due to the rapid clearance of such agents so that the duration of contact at the active site is minimal.

Conventional therapy for periodontal disease, as first enunciated by Pierre Fauchard in 1746 in his book entitled "The Surgeon Dentist, a Treatise on Teeth", involves the mechanical removal of bacterial plaques and accumulations from the periodontal pocket at periodic intervals. This may include periodontal surgery to achieve access and to recontour damaged tissues. These procedures require a high degree of technical expertise from the practitioners of the art, are expensive, and often result in pain, extensive bleeding, and general discomfort on the part of the patient so treated. Since these procedures provide, at best, only temporary reduction in bacterial populations, they must be repeated at regular intervals to be effective. As discussed by Lindhe and coworkers in "Healing

Following Surgical/Non-Surgical Treatment of Periodontal Disease" in the Journal of Clinical Periodontology, vol. 9, pages 115-128, the frequency of repetition needed for optimal results may be as high as once every two weeks.

Methods for administering drugs for periodontal therapy have heretofore largely been concerned with superficial application. For example, long-acting capsules or tablets held in the mouth (see U.S. Pat. No. 3,911,099); buccal implants for releasing drugs into the saliva (see U.S. Patent No. 4,020,558); topically applied gels (see U.S. Pat. No. 3,679,360); topically applied drug-containing bandages (see U.S. Pat. No. 3,339,546); a drug-containing plastic hardenable mass (see U.S. Pat. No. 3,964,164); a medicated periodontal dressing (see U.S. Pat. No. 3,219,527); a topical dressing composed of a finely divided particulate carrier and suspended medicinal agents (see U.S. Pat. No. 3,698,392); a bandage for covering moist mucosal surfaces (see U.S. Pat. No. 3,339,546); a microencapsulated liquid droplet formation for topical application to the gums of dogs and other animals (see U.S. Pat. No. 4,329,333); and foam-film devices containing medication (see U.S. Pat. No. 3,844,286). In addition, several fibrous forms for superficial medication have been described, including impregnated or drug-releasing forms of dental floss (see U.S. Pat. Nos. 3,417,179, 2,667,443, 2,748,781, 3,942,539); solid absorbable fibers of polyglycolic acid with medicants incorporated therein (see U.S. Pat. No. 3,991,766); and cellulose acetate hollow fibers (see U.S. Pat. No. 4,175,326).

Systemic antibiotic therapy for periodontal infections has also been used. In this instance, the objective is to eliminate or suppress growth of specific pathogenic species. Systemic administration of antibiotics starts by selection of the antibiotic with appropriate antibacterial spectrum. Thus, for example, one might administer penicillin to eliminate Gram positive anaerobe infections, metranidazole to eliminate Gram negative anaerobe infections, and tetracycline to eliminate actinobacillus infections. If effective, specific organisms sensitive to the relatively low concentrations of antibiotic achieved by this mode of therapy (ca. 2-10 ug/ml) will be selectively eliminated. Because of the low concentrations of antibiotic achieved by systemic administration and the relative high levels of bacterial resistance associated with periodontal pathogens, the clinical success of this mode of therapy has been poor, as discussed by Genco in "Antibiotics in the Treatment of Human Periodontal Diseases", in J. Periodontology, vol. 52, pages 545-558 (1981).

The article by LANCER and PEPPAS published in the Review of Macromolecular Chemistry and Physics (C23 (1983) No 1, New York, U.S.A.)

generally discusses the chemical and physical structure of polymers as carriers for controlled release of bioactive agents.

Chemical Abstract 97 : 11881s generally relates to a dental feeling comprising a mixture of eugenol and zinc white containing synthetic fibers and various other materials as strengthening agents.

However, this filing material is not a plastic-based therapeutic agent delivering system, and does not appear to contain any pharmaceutical material.

Chemical Abstract 95 : 86264k involves grafting an anesthetic to polymeric fibers.

However, the anesthetic is chemically bonded to the fiber and cannot diffuse from it.

Thus, it appears that none of the previously disclosed procedures has led to an acceptable system for delivering optimally effective levels of antibacterial substances to the site of periodontal disease activity. In addition, it appears that delivery of optimal concentrations of any medicinal agent to disease sites within the periodontal pocket has not been addressed.

A therapeutic agent delivery device is placed within the periodontal pocket in such a manner that the diseased pocket regions come in intimate contact with it. The active agent is thus released at the site of disease, eliminating the variability inherent in long diffusional pathways associated with superficial or systemic treatments. A periodontal pack or other mechanical retaining system keeps the delivery system in this optimal position for the desired period of time. By designing release characteristics of the drug delivery system to provide sustained delivery over a period of days to months, a duration of contact and drug concentration is achieved which results in complete inhibition of all bacterial growth within the periodontal pocket. Upon removal of the therapeutic agent delivery device and the mechanical maintenance device, the periodontal pocket, now devoid of microorganisms, will repopulate in large part from the adjacent oral environment, a microbial population which constitutes organisms of low potential pathogenicity in the periodontal environment. As a result of the altered microbial population, clinical signs of healing are evidenced, including decreased redness, decreased bleeding, reduction of halitosis, elimination of suppuration, elimination of pain, and regeneration of lost connective tissue support for the tooth.

The design and application of devices which employ this therapeutic principle represent a novel approach to the treatment of periodontal disease with the advantages of longer-lasting effectiveness and less pain in application than conventional therapeutic procedures.

Accordingly a first object of the invention is a

therapeutic agent delivery device suitable for continuously delivering a pharmacologically-effective level of therapeutic agent to the site of a periodontal infection within a periodontal pocket, comprising a therapeutic agent selected from the group consisting of immune-suppressive agents, immunestimulatory agents, dentinal desensitizers, odor masking agents, immune reagents, antiinflammatory agents, antibacterials, anesthetics, nutritional agents, antioxidants, lipopolysaccharide complexing agents and peroxides; and a biocompatible polymeric material which is a polymer selected from the group consisting of collagen, glycolic acid polymers, methacrylate polymers, said polymeric material containing said therapeutic material impregnated therein and being permeable to said therapeutic material, the combination of said therapeutic agent and said polymeric material being in the form of a fiber having a diameter of about 0.1 to 1mm.

A second object of the invention is a therapeutic agent delivery and maintenance system suitable for continuously delivering a pharmacologically-effective level of therapeutic agent to the site of a periodontal infection within a periodontal pocket and maintaining it there, comprising :

(a) therapeutic material selected from the group of therapeutic agents consisting of antibacterials, antibiotics, antiinflammatory agents, immune-suppressive agents, immune-stimulatory agents, dentinal desensitizers, odor masking agents, immune reagents, anesthetics, nutritional agents, antioxidants, lipopolysaccharide complexing agents, and peroxides;

(b) biocompatible polymeric material selected from the group of polymers consisting of collagen, cellulosic polymers, glycolic acid polymers, methacrylate polymers, ethylene vinyl acetate copolymers, ethylene vinyl alcohol copolymers, and polycaprolactone ; said polymeric material containing said therapeutic material impregnated therein and being permeable to said therapeutic material ; said polymeric material being in the form of a fiber having a diameter of 0.1 to 1mm and being sufficiently formable and flexible to conform to the site to be treated ; and

(c) means, separate from the therapeutic agent-containing polymeric material, for maintaining said therapeutic agent-containing polymeric material within said periodontal pocket in contact with the site to be treated, said maintaining means also serving to limit diffusion of said therapeutic agent from said pocket.

The invention is illustrated by Figures 1-4 in which:

Fig. 1 illustrates a therapeutic agent delivery device (1) designed to lie totally within the

periodontal pocket between gum (G) and tooth (T). It is held in place by mechanical locking, by elastic retention, by adhesive properties intrinsic to the plastic, or by a suitable adhesive. This delivery system is in contact with saliva (2), to which some of the therapeutic material can diffuse.

Fig. 2 illustrates a form of therapy in which an inert conforming dressing (3) overlies the delivery device (1) to hold the device in place and limit diffusional loss of the therapeutic agent into the salivary compartment.

Fig. 3 illustrates an alternative form of mechanical retention, in which an elastic band of biocompatible material (4) serves to occlude the pocket orifice and mechanically retain the delivery device.

Fig. 4 illustrates an alternative form in which an annular formed elastic therapeutic agent delivery device (1) with a diffusion-limiting outer surface (5) is designed to lie wholly or in part in a shallow periodontal pocket or sulcus.

The invention relates to a therapeutic agent delivery device intended to be placed within the periodontal pocket so that release of the therapeutic agents occurs in the immediate vicinity of the disease process. As the volume of distribution is limited to the total volume of gingival crevice fluid produced within the periodontal pocket, relatively high concentrations of therapeutic agent are developed in the pocket by devices with small therapeutic agent capacities. The small amount of therapeutic agent required under these conditions; typically a few milligrams, greatly reduces the effect of the therapeutic agent at distal sites within the body, thereby greatly decreasing the potential for systemic side effects. By establishing local concentrations of an antibacterial agent sufficient to inhibit growth of all bacteria within the pocket, development of drug resistant strains is minimized. The potential for encouraging the development of drug-resistant pathogens is further minimized by the relatively short duration to achieve the desired effect, typically on the order of three to ten days. By this procedure, therapeutic agent delivery devices containing a few milligrams of therapeutic agents are capable of rendering effects greater than would be expected by the same drug used at much higher doses by other routes of administration. This principle results in an unexpectedly high degree of effectiveness from the comparatively small amount of drug utilized.

The use of a periodontal or other mechanical retaining and/or diffusion-limiting device further enhances therapeutic effectiveness. This aspect of the method of treatment has the primary function of maintaining the delivery device in an optimal position to render its effect. A second function is to reduce diffusion of therapeutic agent and therefore

reduce loss of the agent into the saliva. The restriction of therapeutic agent diffusion into saliva further reduces possible side effects which could conceivably occur in the oral cavity or in the gastrointestinal tract.

The local delivery devices useful in the invention comprise therapeutic materials in a matrix of biocompatible semipermeable polymeric material. By proper selection of the polymeric material and therapeutic material, blends may be obtained from which the therapeutic material will diffuse at a controlled rate over selected periods of time.

A wide variety of semipermeable biocompatible natural or synthetic polymers, such as collagen, cellulosic polymers, glycolic acid polymers, methacrylate polymers, ethylene vinyl acetate polymers, ethylene vinyl alcohol copolymers, polycaprolactone, etc., may provide the polymeric substance for the local delivery device. These materials may be fabricated into a variety of shapes, including slabs, strips, films, ribbons, or fibers, and may have various consistencies, including solids, gels, plastic, granular aggregates, microsphere preparations, and spongy forms capable of being formed or introduced into the periodontal pocket.

It is recognized that in the fabrication of local delivery devices, certain inert substances may be included to modify the delivery characteristics or serve as carriers of the active agent, including solvents, suspending agents, surfactants, viscosity-controlling agents, complexing agents, antioxidants, antibacterials, and other pharmaceutically acceptable materials which may be employed to solubilize or stabilize the materials in the polymeric matrix and control the rate of permeation or the action of the materials after permeation.

This invention is not limited to the use of antibacterial agents alone. A wide variety of therapeutic agents may be used in the invention. Some therapeutic agents which are amenable to delivery by this means and are potentially of value for periodontal therapy, include anti bacterial agents such as iodine, sulfonamides, mercurials, bisbiguanides, or phenolics; antibiotics such as tetracycline, neomycin, kanamycin, metranidazole, or canamycin; anti-inflammatory agents such as indomethacin, eugenol, or hydrocortisone; immunosuppressive or stimulatory agents such as methotrexate or levamisole; dental desensitizing agents such as strontium chloride or sodium fluoride; odor masking agents such as peppermint oil or chlorophyll; immune reagents such as immunoglobulin or antigens; local anaesthetic agents such as lidocaine or benzocaine; nutritional agents such as amino acids, essential fats, and vitamin C; antioxidants such as alphanatocopherol and butylated hydroxy toluene; lipopolysaccharide complexing agents such as polymyxin; or peroxides such as

urea peroxide. It is recognized that in certain forms of therapy, combinations of these agents in the same delivery system may be useful in order to obtain an optimal effect. Thus, for example, an antibacterial and an anti-inflammatory agent may be combined in a single delivery system to provide combined effectiveness.

The means for mechanical maintenance of the delivery system (hereafter, maintenance system) generally serves not only to hold the therapeutic agent delivery device in place, but also to prevent or reduce diffusion of the therapeutic agent out of the periodontal pocket. It can take a variety of forms; for example, an inert periodontal dressing, and elastic band of suitable biocompatible material, an elastic sheet, an adhesive film or gel, or a metallic or polymeric cover. It may be biodegradable, thus eventually allowing the therapeutic agent delivery device to be washed out of the periodontal pocket by gingival fluid flow, thereby terminating therapy. In addition, it may itself provide a therapeutic agent delivery function which could, for example, serve to decrease bacterial or fungal accumulations, reduce local inflammation, or mask mouth odors. The maintenance system can be fastened in place by any suitable means, including self-adhesion, melting, cementing, crimping, etc.

The maintenance system may also be intrinsic to the therapeutic agent delivery device for example, where the delivery device itself has adhesive properties or possesses a springiness which would cause it to be retained in the periodontal pocket once it has been inserted into the pocket in a compressed state.

Experimental determination of the concentration of tetracycline necessary to suppress the growth of all cultivable periodontal microorganisms: Samples containing periodontal organisms taken from deep periodontal pockets of 5 patients were transferred to 10 ml of pre-reduced Ringer's solution, dispersed by 10 seconds of sonic oscillation at an amplitude of 10 microns, and dilutions of 1:20, 1:100, and 1:1000 were prepared. One-tenth milliliter of each dilution was streaked on trypticase soy agar containing 5% sheep blood and 0.3 ug/ml menadione in petrie dishes. Identical plates were prepared containing 1, 8, 32, and 64 micrograms/milliliter of tetracycline hydrochloride. Inoculated plates were incubated at 35°C in an anaerobic atmosphere at 80% nitrogen, 10% hydrogen, and 10% carbon dioxide for 5 to 7 days. Plates from dilutions providing separated colony growth were selected for counting to determine the total colony forming units on primary medium and each associated tetracycline-containing medium. Percentages of organisms grown at each concentration were computed. Values of 21.2%, 3.6%,

0.08%, and 0% were found on plates containing 1, 8, 32, and 64 micrograms/milliliter tetracycline respectively. These observations indicate that no cultivable periodontal organisms grow at tetracycline concentrations of 64 micrograms/milliliter, thereby establishing the primary design parameter for a local drug delivery system for periodontal therapy which would suppress growth of all cultivable periodontal microorganisms with continuous exposure of the organisms to tetracycline.

Preparation of a therapeutic agent delivery device containing tetracycline as the therapeutic agent :

The chamber of a Tinius Olsen Extrusion Plastometer, with a spinneret inserted, was preheated to approximately 180°C, a temperature below the temperature at which tetracycline hydrochloride decomposes. It was then loaded with a mixture of 25% by weight of tetracycline hydrochloride in ethylene vinyl acetate copolymer (45% vinyl acetate, melt index 7.5g/10 min), and an extrusion ram with weights attached was inserted into the chamber to compress the mixture while it equilibrated. After equilibration, additional weights were added to the ram to force the molten material through the spinneret. As the material was extruded, it cooled to form fibers which were collected in loose coils. Fibers so prepared were approximately 0.5 mm in diameter, contained about 300 ug of tetracycline hydrochloride per centimeter, and were elastic and slightly tacky.

In vitro release of tetracycline hydrochloride from ethylene vinyl acetate copolymer fibers :

Triplicate samples of ethylene vinyl acetate copolymer fibers containing about 300 ug of tetracycline hydrochloride per cm were immersed in separate flasks containing 25 or 50 ml aliquots of deionized water, the containers were sealed, and the mixtures were agitated gently at 37°C on a shaking water bath. Three-ml aliquots of the receiving fluid were periodically sampled and assayed for tetracycline hydrochloride by measuring the absorption peak at 278nm on a Perkin-Elmer 575 spectrophotometer. A 3-ml aliquot of deionized water was added to the receiving fluid of each vessel sampled to replace the volume removed. The amount of tetracycline released was determined from a Beer's Law plot derived from the absorbance of known concentrations of tetracycline hydrochloride. Such tests showed that the fibers tested possessed non-linear release characteristics, sustaining delivery for 9 days under the experimental conditions. The apparent permeability constant obtained from Fick's Law of diffusion as applied to cylindrical geometry was  $7.1 \times 10^{-12} \text{ gm cm}^{-1} \text{ sec}^{-1}$ . The approximation of drug release rate during the first day was 100 ug/cm, and over days 2 through 9 it was approximately 25 ug/cm/day. Assay for tetracycline in gingival fluid:

Samples of gingival fluid were taken by intracrevicular sampling technique using filter paper strips (Harco periotron). The relative volume of the sample was measured by the change in dielectric constant of the filter paper (Harco Periotron) and the volume was computed from a standard response obtained from serum. The amount of tetracycline on the filter paper sample was determined by comparing the diameter of inhibition of growth of *Bacillus cereus* caused by the placement of the filter paper on an inoculated plate with the zone of inhibition of standards applied in the same manner. Assay plates were made by inoculating 10 ml of Todd Hewitt broth with *B. cereus* and incubating overnight at 37°C. Mueller-Hinton broth with 1.5% agar was autoclaved and cooled to 50°C. The medium was seeded by adding 2 ml of inoculum to each 100 ml of the cooled broth-agar. Assay plates were made by pipeting 7 ml of the seeded broth-agar medium into 100 mm diameter plastic petri dishes. The assay was performed by placing filter paper strips with either unknowns or standards on the solidified surface of assay plates and incubating at 37°C overnight.

Tetracycline standards at concentrations of 500, 200, 100, 50, 25 and 12.5 ug/ml were prepared from a 1 mg/ml of stock solution by diluting with pH 7 phosphate with 3.5% bovine serum albumin. A 0.5 ul aliquot of each standard was applied on identical filter paper samples using a 1 ul syringe. The diameter of the zone of inhibition of triplicate or quadruplicate standards was measured to the nearest mm. A standard response function was derived by computing the linear least-squares fit of the diameter of growth inhibition as a function of the fourth root of the amount of tetracycline applied. Analysis of variance of regression of the least-squares fit function for N=66 standard samples indicated that it provided a satisfactory fit to the data. The correlation ratio of the linear regression component was 0.951, indicating that the fitted function explained 95% of the observed variation. The average standard deviation of multiple standards was 0.59 mm with no systematic dependence on the amount of tetracycline applied. The fourth order polynomial solution of least-squares fit function was used to compute the amount of tetracycline in gingival fluid samples from the measured zone diameter. This assay provided a measurable response for samples containing between 6 and 250 ng of tetracycline allowing concentrations from 6 to 2500 ug/ml to be determined from Sample volumes of 0.1 to 1.0 ul. Concentration was calculated by dividing the nanogram amount as estimated by bioassay by the volume as determined by the gingival fluid meter. Periodontal treatment; example No. 1:

When a relatively shallow (5 mm) periodontal

pocket was packed with ethylene vinyl acetate copolymer containing about 300 ug of tetracycline hydrochloride per centimeter, no covering being employed, an initial concentration of tetracycline, as measured by microbiologic assay of gingival fluid samples, of 650 ug/ml was established with a concentration half-time of 13 hours. In this instance, the treated periodontal pocket was initially populated by approximately  $10^{-6}$  spirochetes per standardized microbiologic sample, bled spontaneously, and was characterized by pus formation. Following fiber placement for 10 days, the spirochetal component was no longer detectable by darkfield microscopy. Within one month, the periodontal pocket had healed, leaving a physiologic 3 mm sulcus. All signs of disease disappeared and the site remained clinically healthy during subsequent examination for the following year. These observations indicated that as a result of placement of the therapeutic agent delivery device into the periodontal pocket, a long-term clinical change was associated with a permanent alteration of the microbial ecology of the region. Periodontal treatment; example No. 2:

The therapeutic agent delivery device of treatment Example 1 was placed into a suppurant, deep (8mm) periodontal pocket by forcing the fiber into the pocket in such a manner that the irregular pocket geometry was completely filled with the delivery material. This region was then overlaid by a dressing made of zinc-oxide and eugenol. This dressing material, commonly used as an intra-oral bandage by practitioners, was mixed as a combination of liquid and powder which rapidly hardens in the mouth to form an inert mass which conforms to the irregular boundaries of the neck of the tooth and adjacent gum tissue. By so doing, the tetracycline-loaded delivery device already forced deep into the pocket was maintained in close proximity to the active disease site for a total of 10 days. At the time of removal of the periodontal dressing and the underlying drug delivery device the concentration of the tetracycline in gingival fluid as approximately 1000 micrograms/milliliter (0.1%), indicating that higher levels of drug were maintained over the therapeutic period when the delivery device is covered by a periodontal dressing.

At the time of removal, the periodontal tissues appeared less inflamed. One month later, the pocket depth measured 4 mm, representing a major improvement in connective tissue attachment to the tooth. Over the remaining 6 months of observation, the site continued to appear clinically healthy. Periodontal treatment; example No. 3:

One periodontal pocket in each of 6 patients was treated as described in Example 2. Microbiologic changes associated with the treatment were evaluated by determining the Gram staining

properties of 50 randomly selected isolates derived from blood-agar primary isolation plates incubated in an anaerobic environment. Before treatment, 56% of the organisms isolated were Gram positive; one month later, 71% were Gram positive. These observations indicate that a major microbiologic alteration occurred as a result of the local antibacterial therapy administered in the preceeding month. The significant change in percentage composition indicates that an ecologic alteration has resulted from the therapy.

## Claims

1. A therapeutic agent delivery device suitable for continuously delivering a pharmacologically-effective level of therapeutic agent to the site of a periodontal infection within a periodontal pocket, comprising a therapeutic agent selected from the group consisting of immune-suppressive agents, immune-stimulatory agents, dentinal desensitizers, odor masking agents, immune reagents, antiinflammatory agents, antibacterials, anesthetics, nutritional agents, antioxidants, lipopolysaccharide complexing agents and peroxides in an amount of 10% to 50% by weight of said device; and a biocompatible polymeric material which is a polymer selected from the group consisting of collagen, glycolic acid polymers, methacrylate polymers, said polymeric material containing said therapeutic material impregnated therein and being semi permeable to said therapeutic materials, the combination of said therapeutic agent and said polymeric material being in the form of a fiber having a diameter of 0.1 to 1mm.

2. The therapeutic agent delivery device of claim 1 wherein the fiber has a diameter of about 0.5mm.

3. A therapeutic agent delivery and maintenance system suitable for continuously delivering a pharmacologically-effective level of therapeutic agent to the site of a periodontal infection within a periodontal pocket and maintaining it there, comprising:

(a) therapeutic material selected from the group of therapeutic agents consisting of antibacterials, antibiotics, antiinflammatory agents, immune-suppressive agents, immune-stimulatory agents, dentinal desensitizers, odor masking agents, immune reagents, anesthetics, nutritional agents, antioxidants, lipopolysaccharide complexing agents, and peroxides;

(b) biocompatible polymeric material selected from the group of polymers consisting of collagen, cellulosic polymers, glycolic acid polymers, methacrylate polymers, ethylene vinyl acetate copolymers, ethylene vinyl alcohol copolymers, and polycaprolactone, said polymeric material containing said therapeutic material impregnated therein and being semi permeable to said therapeutic material said polymeric material being in the form of a fiber having a diameter of 0.1 to 1mm, containing 10% to 50% by weight of said therapeutic material and being sufficiently formable and flexible to conform to the site to be treated; and

(c) means, separate from the therapeutic agent-containing polymeric material, for maintaining said therapeutic agent-containing polymeric material within said periodontal pocket in contact with the site to be treated, said maintaining means also serving to limit diffusion of said therapeutic agent from said pocket.

4. The therapeutic agent delivery and maintenance system of claim 3 wherein the therapeutic material is tetracycline or a pharmaceutically-acceptable acid addition salt thereof; and the polymeric material is an ethylene vinyl acetate copolymer.

5. The therapeutic agent delivery and maintenance system of any of claims 3 to 4 wherein said means for maintaining the therapeutic agent-containing material in the periodontal pocket comprises an inert periodontal dressing

6. The therapeutic agent delivery and maintenance system of any of claims 3 to 4 wherein said means for maintaining the therapeutic agent-containing material in the periodontal pocket comprises a biocompatible polymeric material.

7. The therapeutic agent delivery and maintenance system of any of claims 3 to 4 wherein said means for maintaining the therapeutic agent-containing material in the periodontal pocket comprises a metal cap.

8. The therapeutic agent delivery and maintenance system of any of claims 3 to 4 wherein said means for maintaining the therapeutic agent-containing material in the periodontal pocket comprises an elastic band.

9. The therapeutic agent delivery and maintenance system of any of claims 3 to 8 wherein

said means for maintaining the therapeutic agent-containing material in the periodontal pocket comprises an adhesive.

10. A therapeutic agent delivery system suitable for continuously delivering a pharmacologically effective level of therapeutic agent to the site of a periodontal infection within a periodontal pocket and maintaining it there, comprising:

a fiber of an ethylene vinyl acetate copolymer, said fiber having a diameter of 0.1 to 1mm and containing tetracycline or a pharmaceutically-acceptable acid addition salt thereof impregnated therein at a level of 10 to 50% by weight; and

means, separate from said tetracycline-containing fiber, for maintaining said tetracycline-containing fiber within said periodontal pocket in contact with the site to be treated, said maintaining means also serving to limit diffusion of said therapeutic agent from said pocket.

#### Revendications

1. Dispositif d'apport d'agent thérapeutique permettant la libération continue d'une concentration pharmacologiquement efficace d'agent thérapeutique au site d'une infection parodontale à l'intérieur d'une poche parodontale, comprenant un agent thérapeutique sélectionné dans le groupe comprenant des immunosuppresseurs, des immunostimulants, des désensibilisants dentinaires, des déodorants, des réactifs immunologiques, des anti-inflammatoires, des antibactériens, des anesthésiques, des agents nutritionnels, des anti-oxydants, des complexants des lipopolysaccharides et des peroxydes en une quantité représentant 10 % à 50 % en poids dudit dispositif et un matériau polymère biocompatible qui est un polymère sélectionné dans le groupe composé du collagène, de polymères de l'acide glycolique, de polymères du méthacrylate, ledit matériau polymère étant imprégné de ladite substance thérapeutique et étant semi-perméable à ladite substance thérapeutique, l'association dudit agent thérapeutique et dudit matériau polymère ayant la force d'une fibre de 0,1 à 1 mm de diamètre.
2. Dispositif d'apport d'agent thérapeutique selon la revendication 1, dans lequel la fibre a un diamètre d'environ 0,5 mm.
3. Système d'apport et de maintien d'agent thérapeutique permettant la libération continue

d'une concentration pharmacologiquement efficace d'agent thérapeutique au site d'une infection parodontale à l'intérieur d'une poche parodontale et son maintien, comprenant:

(a) une substance thérapeutique sélectionnée dans le groupe d'agents thérapeutiques constitué par des antibactériens, des antibiotiques, des anti-inflammatoires, des immunosuppresseurs, des immunostimulants, des désensibilisants dentinaires, des déodorants, des réactifs immunologiques, des anesthésiques, des agents nutritionnels, des anti-oxydants, des complexants des lipopolysaccharides et des peroxydes;

(b) un matériau polymère biocompatible sélectionné dans le groupe des polymères comprenant le collagène, les polymères cellulose, les polymères de l'acide glycolique, les polymères du méthacrylate, les copolymères éthylène-acétate de vinyle, les copolymères éthylène-alcool vinylique et la polycaprolactone; ledit matériau polymère étant imprégné de ladite substance thérapeutique et étant semi-perméable à ladite substance thérapeutique; ledit matériau polymère se présentant sous la forme d'une fibre de 0,1 et 1 mm de diamètre, contenant de 10 % à 50 % en poids de ladite substance thérapeutique et étant suffisamment malléable et flexible pour s'adapter au site à traiter; et

(c) un dispositif, distinct du matériau polymère contenant l'agent thérapeutique, destiné à maintenir ledit matériau polymère contenant l'agent thérapeutique à l'intérieur de ladite poche parodontale en contact avec le site à traiter, ledit dispositif de maintien servant également à limiter la diffusion dudit agent thérapeutique à partir de ladite poche.

4. Système d'apport et de maintien d'agent thérapeutique selon la revendication 3, dans lequel la substance thérapeutique est de la tétracycline ou un sel d'addition d'acide pharmaceutiquement acceptable de celle-ci; et le matériau polymère est un copolymère éthylène-acétate de vinyle.

5. Système d'apport et de maintien d'agent thérapeutique selon l'une quelconque des revendications 3 et 4, dans lequel ledit dispositif de maintien du matériau contenant l'agent thérapeutique dans la poche parodontale comprend un pansement parodontal inerte.

6. Système d'apport et de maintien d'agent thérapeutique selon l'une quelconque des revendi-

cations 3 et 4, dans lequel ledit dispositif de maintien du matériau contenant l'agent thérapeutique dans la poche parodontale comprend un matériau polymère biocompatible.

7. Système d'apport et de maintien d'agent thérapeutique selon l'une quelconque des revendications 3 et 4, dans lequel ledit dispositif de maintien du matériau contenant l'agent thérapeutique dans la poche parodontale comprend un capuchon métallique.

8. Système d'apport et de maintien d'agent thérapeutique selon l'une quelconque des revendications 3 et 4, dans lequel ledit dispositif de maintien du matériau contenant l'agent thérapeutique dans la poche parodontale comprend une bande élastique.

9. Système d'apport et de maintien d'agent thérapeutique selon l'une quelconque des revendications 3 à 8, dans lequel ledit dispositif de maintien du matériau contenant l'agent thérapeutique dans la poche parodontale comprend un adhésif.

10. Système d'apport d'agent thérapeutique permettant la libération continue d'une concentration pharmacologiquement efficace d'agent thérapeutique au site d'une infection parodontale à l'intérieur d'une poche parodontale et son maintien, comprenant:

une fibre d'un copolymère éthylène-acétate de vinyle, ladite fibre ayant un diamètre de 0,1 à 1 mm et étant imprégnée de tétracycline ou d'un sel d'addition d'acide pharmaceutiquement acceptable de celle-ci en une concentration comprise entre 10 et 50 % en poids; et

un dispositif, distinct de ladite fibre contenant la tétracycline, de maintien de ladite fibre contenant la tétracycline à l'intérieur de ladite poche parodontale en contact avec le site à traiter, ledit dispositif de maintien servant également à limiter la diffusion dudit agent thérapeutique à partir de ladite poche.

#### Ansprüche

1. Vorrichtung zur Abgabe therapeutischer Mittel zur kontinuierlichen Bereitstellung eines pharmakologisch wirksamen Pegels des therapeutischen Mittels an die Stelle einer periodontalen Infektion innerhalb einer periodontalen Tasche, die ein therapeutisches Mittel, das unter immunsuppressiven Mitteln, immunstimulieren-

den Mitteln, dentalen Desensibilisatoren, Geruchsmaskierungsmitteln, Immunreagentien, entzündungshemmenden Mitteln, antibakteriellen Mitteln, Anästhetika, Mitteln zur Ernährung, Antioxidantien, Lipopolysacchariden, Komplexbildnern und Peroxiden ausgewählt ist, in einer Menge von 10 bis 50 Gew.-%, bezogen auf das Gewicht der Vorrichtung, und ein biokompatibles Polymermaterial enthält, das ein unter Collagen, Glykolsäurepolymeren und Methacrylatpolymeren ausgewähltes Polymer darstellt, welches das darin einimpregnierete therapeutische Material enthält und ihm gegenüber semipermeabel ist, wobei die Kombination des therapeutischen Mittels und des Polymermaterials in Form einer Faser mit einem Durchmesser von 0,1 bis 1 mm vorliegt.

2. Vorrichtung zur Abgabe therapeutischer Mittel nach Anspruch 1, wobei die Faser einen Durchmesser von etwa 0,5 mm besitzt.

3. Vorrichtung zur Abgabe therapeutischer Mittel sowie Haltesystem zur kontinuierlichen Bereitstellung eines pharmakologisch wirksamen Pegels des therapeutischen Mittels an die Stelle einer periodontalen Infektion innerhalb einer periodontalen Tasche und zum Halten dieser Vorrichtung an dieser Stelle, die enthält:

(a) ein therapeutisches Material, das unter antibakteriellen Mitteln, Antibiotika, entzündungshemmenden Mitteln, immunsuppressiven Mitteln, immunstimulierenden Mitteln, Dentin-Desensibilisierungsmitteln, Geruchsmaskierungsmitteln, Immunreagentien, Anästhetika, Mittel zur Ernährung, Antioxidantien, Lipopolysacchariden, Komplexbildnern und Peroxiden ausgewählt ist;

(b) ein biokompatibles Polymermaterial, das ein unter Collagen, Cellulosepolymeren, Glykolsäurepolymeren, Methacrylatpolymeren, Ethylen-Vinylacetat-Copolymeren, Ethylen-Vinylalkohol-Copolymeren und Polycaprolactonen ausgewähltes Polymer darstellt, welches das darin einimpregnierete therapeutische Material enthält und ihm gegenüber semipermeabel ist, wobei das Polymermaterial in Form einer Faser mit einem Durchmesser von 0,1 bis 1 mm vorliegt, 10 bis 50 Gew.-% des therapeutischen Materials enthält und ausreichend formbar und flexibel ist, so daß es an die zu behandelnde Stelle anpaßbar ist, und

(c) von dem das therapeutische Mittel enthaltenden Polymermaterial getrennte Mittel zum Halten des das therapeutische Mittel enthaltenden Polymermaterials innerhalb der periodontalen Tasche im Kontakt mit

der zu behandelnden Stelle, wobei die Haltemittel auch zur Begrenzung der Diffusion des therapeutischen Mittels aus der Tasche dienen.

4. Vorrichtung zur Abgabe therapeutischer Mittel und Haltesystem nach Anspruch 3, wobei das therapeutische Material Tetracyclin oder ein pharmazeutisch akzeptables Säureadditionssalz davon darstellt und das Polymermaterial ein Ethylen-Vinylacetat-Copolymer ist. 5  
10
5. Vorrichtung zur Abgabe therapeutischer Mittel und Haltesystem nach Anspruch 3 oder 4, wobei die Mittel zum Halten des das therapeutische Mittel enthaltenden Materials in der periodontalen Tasche einen inertten Periodontalverband umfaßt. 15
6. Vorrichtung zur Abgabe therapeutischer Mittel und Haltesystem nach Anspruch 3 oder 4, wobei die Mittel zum Halten des das therapeutische Mittel enthaltenden Materials in der periodontalen Tasche ein biokompatibles Polymermaterial umfassen. 20  
25
7. Vorrichtung zur Abgabe therapeutischer Mittel und Haltesystem nach Anspruch 3 oder 4, wobei die Mittel zum Halten des das therapeutische Mittel enthaltenden Materials in der periodontalen Tasche eine Metallkappe umfassen. 30
8. Vorrichtung zur Abgabe therapeutischer Mittel und Haltesystem nach Anspruch 3 oder 4, wobei die Mittel zum Halten des das therapeutische Mittel enthaltenden Materials in der periodontalen Tasche ein elastisches Band umfassen. 35  
40
9. Vorrichtung zur Abgabe therapeutischer Mittel und Haltesystem nach einem der Ansprüche 3 bis 8, wobei die Mittel zum Halten des das therapeutische Mittel enthaltenden Materials in der periodontalen Tasche einen Kleber umfassen. 45
10. Vorrichtung zur Abgabe therapeutischer Mittel zur kontinuierlichen Bereitstellung eines pharmakologisch wirksamen Pegels des therapeutischen Mittels an die Stelle einer periodontalen Infektion innerhalb einer periodontalen Tasche und zum Halten an dieser Stelle; die umfaßt:  
Eine Faser aus einem Ethylen-Vinylacetat-Copolymer mit einem Durchmesser von 0,1 bis 1 mm, die Tetracyclin oder ein pharmazeutisch akzeptables Säureadditionssalz davon in einer Menge von 10 bis 50 Gew.-% 50  
55

einimprägniert enthält, und von der Tetracyclin enthaltenden Faser getrennte Mittel zum Halten der Tetracyclin enthaltenden Faser innerhalb der periodontalen Tasche im Kontakt mit der zu behandelnden Stelle, wobei die Haltemittel auch zur Begrenzung der Diffusion des therapeutischen Mittels aus der Tasche dienen.
